

Minimum Spanning Trees

- Minimum Spanning Trees
- Kruskal's Algorithm
- Prim's Algorithm
- Sidetrack: Priority Queues
- Other MST Algorithms

❖ Minimum Spanning Trees

Reminder: **Spanning tree** ST of graph $G=(V,E)$

- **spanning** = all vertices, **tree** = no cycles
- ST is a subgraph of G ($G'=(V,E')$ where $E' \subseteq E$)
- ST is **connected** and **acyclic**

Minimum spanning tree MST of graph G

- MST is a spanning tree of G
- sum of edge weights is no larger than any other ST

Applications:

- Computer networks, Electrical grids, Transportation networks ...

❖ ... Minimum Spanning Trees

Example:

Original Graph

A Spanning Tree

Minimum Spanning Tree

no vertex no cycle

❖ ... Minimum Spanning Trees

Problem: how to (efficiently) find MST for graph G ?

One possible strategy:

- generate all spanning trees
- calculate total weight of each
- MST = ST with lowest total weight

Note that MST may not be unique

- e.g. if all edges have same weight, then all STs are MSTs

❖ ... Minimum Spanning Trees

Brute force solution (using generate-and-test strategy):

```
findMST(G):  
  Input  graph G  
  Output a minimum spanning tree of G  
  
  bestCost = ∞  
  for all spanning trees t of G do  
    if cost(t) < bestCost then  
      bestTree = t  
      bestCost = cost(t)  
    end if  
  end for  
  return bestTree
```

Not useful in general because #spanning trees is potentially large
(e.g. n^{n-2} for a complete graph with n vertices)

❖ ... Minimum Spanning Trees

Simplifying assumption:

- edges in G are not directed (MST for digraphs is harder)

direct harder

If edges are not weighted

- there is no real notion of *minimum* spanning tree

no negative weight

没概念

Our MST algorithms apply to

- weighted, non-directional, connected graphs

❖ Kruskal's Algorithm

One approach to computing MST for graph G with V nodes:

1. start with empty MST
2. consider edges in increasing weight order
 - add edge if it does not form a cycle in MST
3. repeat until $V-1$ edges are added

$a-b-5$
 $b-c-7$
 $a-d-10$
 $a-c-12$

Critical operations:

- iterating over edges in weight order
- checking for cycles in a graph

❖ ... Kruskal's Algorithm

DFS

Execution trace of Kruskal's algorithm:

Original

After step 1

After step 2

After step 3

After step 4a

After step 4b

❖ ... Kruskal's Algorithm

Pseudocode:

```
KruskalMST(G):
  Input  graph G with n nodes
  Output a minimum spanning tree of G

  MST=empty graph
  sort edges(G) by weight
  for each e ∈ sortedEdgeList do
    MST = MST ∪ {e} // add edge
    if MST has a cycle then
      MST = MST \ {e} // drop edge
    end if
    if MST has n-1 edges then 都有了
      return MST
    end if
  end for
```

❖ ... Kruskal's Algorithm

Rough time complexity analysis ...

- sorting edge list is $O(E \cdot \log E)$
- at least V iterations over sorted edges
- on each iteration ...
 - getting next lowest cost edge is $O(1)$
 - checking whether adding it forms a cycle: cost = $O(V^2)$

$$O(V^2 + E \cdot \log E)$$

Possibilities for cycle checking:

- use DFS ... too expensive?
- could use *Union-Find data structure* (see Sedgewick Ch.1)

❖ Prim's Algorithm

BFS

Another approach to computing MST for graph $G=(V,E)$:

1. start from any vertex v and empty MST
2. choose edge not already in MST to add to MST; must be:
 - incident on a vertex s already connected to v in MST *inside*
 - incident on a vertex t not already connected to v in MST *outside*
 - minimal weight of all such edges
3. repeat until MST covers all vertices

Critical operations:

- checking for vertex being connected in a graph
- finding min weight edge in a set of edges

❖ ... Prim's Algorithm

Execution trace of Prim's algorithm (starting at $s=0$):

Start of step 1

End of step 1

Start of step 2

End of step 2

Start of step 3

End of step 3

Start of step 4

End of step 4

MST

❖ ... Prim's Algorithm

Pseudocode:

PrimMST(G) :

Input graph G with n nodes

Output a minimum spanning tree of G

MST=empty graph

usedV={0}

unusedE=edges(g)

while |usedV| < n **do** *edge(g)*

find $e=(s,t,w) \in \text{unusedE}$ **such that** {
 $s \in \text{usedV} \wedge t \notin \text{usedV}$
 $\wedge w$ is min weight of all such edges

 }

 MST = MST \cup {e} *+*

 usedV = usedV \cup {t} *t in usedV*

 unusedE = unusedE \setminus {e} *drop e*

end while

return MST

Critical operation: finding best edge

❖ ... Prim's Algorithm

Rough time complexity analysis ...

- V iterations of outer loop
- in each iteration, finding min-weighted edge ...
 - with set of edges is $O(E) \Rightarrow O(V \cdot E)$ overall
 - with priority queue is $O(\log E) \Rightarrow O(V \cdot \log E)$ overall

Note:

- have seen stack-based (DFS) and queue-based (BFS) traversals
- using a *priority queue* gives another non-recursive traversal

❖ Sidetrack: Priority Queues

Some applications of queues require

- items processed in order of "key"
- rather than in order of entry (FIFO — first in, first out)

Priority Queues (PQueues) provide this via:

- **join**: insert item into PQueue (replacing **enqueue**)
- **leave**: remove item with largest key (replacing **dequeue**)

Will discuss priority queues in more detail in another video

❖ Other MST Algorithms

Boruvka's algorithm ... complexity $O(E \cdot \log V)$

- the oldest MST algorithm
- start with V separate components
- join components using min cost links
- continue until only a single component

Karger, Klein, and Tarjan ... complexity $O(E)$

- based on Boruvka, but non-deterministic
- randomly selects subset of edges to consider
- for the keen, here's [the paper](#) describing the algorithm
