Analysis of Algorithms ◇ COMP2521 (20T3) ◇ Week 01b ◇ [0/60]

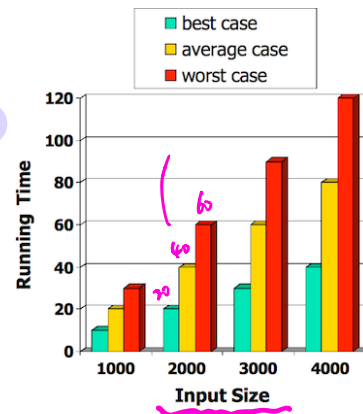

❖ Running Time

An ^{算法}algorithm is a step-by-step procedure

- for solving a problem
- in a finite amount of time

Most algorithms map input to output

- running time typically grows with input size
- average time often difficult to determine
- Focus on worst case running time
 - easier to analyse
 - crucial to many applications: finance, robotics, games, ...

❖ Empirical Analysis

1. Write program that implements an algorithm
2. Run program with inputs of varying size and composition
3. Measure the actual running time
4. Plot the results

❖ ... Empirical Analysis

Limitations:

- requires to implement the algorithm, which may be difficult
- results may not be indicative of running time on other inputs
- same hardware and operating system must be used in order to compare two algorithms

must use same

❖ Theoretical Analysis

- Uses high-level description of the algorithm instead of implementation ("pseudocode") 伪代码
- Characterises running time as a function of the input size, n
- Takes into account all possible inputs
- Allows us to evaluate the speed of an algorithm independent of the hardware/software environment

独立于硬件及软件来评估算法速度

❖ Pseudocode 伪代码

- More structured than English prose 散文
- Less detailed than a program
- Preferred notation for describing algorithms
- Hides program design issues

❖ ... Pseudocode

Example: Find **maximal** element in an array

```
arrayMax(A) :  
|   Input   array A of n integers  
|   Output maximum element of A  
  
|   currentMax=A[0]  
|   for all i=1..n-1 do  
|   |   if A[i]>currentMax then  
|   |       currentMax=A[i]  
|   |   end if  
|   end for  
|   return currentMax
```

❖ ... Pseudocode

Control flow

- if ... then ... [else] ... end if
- while .. do ... end while
 repeat ... until
 for [all][each] .. do ... end for

Function declaration

- f(arguments):
 Input ...
 Output ...
 ...

Expressions

- = assignment 赋值
- = equality testing
- n^2 superscripts and other mathematical formatting allowed
- swap A[i] and A[j] verbal descriptions of simple operations allowed

❖ Exercise : Pseudocode

Formulate the following verbal description in pseudocode:

In the first ^{阶段} phase, we iteratively pop all the elements from stack S and enqueue them in queue Q , then dequeue the element from Q and push them back onto S .

As a result, all the elements are now in reversed order on S .

In the second phase, we again pop all the elements from S , but this time we also look for the element x .

By again passing the elements through Q and back onto S , we reverse the reversal, thereby restoring the original order of the elements on S .

<< ^ >>

Sample solution:

```
while ¬empty(S) do
  pop e from S, enqueue e into Q
end while
while ¬empty(Q) do
  dequeue e from Q, push e onto S
end while
found=false
while ¬empty(S) do
  pop e from S, enqueue e into Q
  if e=x then
    found=true
  end if
end while
while ¬empty(Q) do
  dequeue e from Q, push e onto S
end while
```

Analysis of Algorithms ◇ COMP2521 (20T3) ◇ Week 01b ◇ [9/60]

❖ Exercise : Pseudocode

Implement the following pseudocode instructions in C

- **A** is an array of ints

```
...  
swap A[i] and A[j]  
...
```

- **head** points to beginning of linked list

```
...  
swap head and head->next  
...
```

- **S** is a stack

```
...  
swap the top two elements on S  
...
```

1.

```
int temp = A[i];
A[i] = A[j];
A[j] = temp; = A[i]
```
2.

```
NodeT *succ = head->next;
head->next = succ->next;
succ->next = head;
head = succ;
```
3.

```
x = StackPop(S);
y = StackPop(S);
StackPush(S, x);
StackPush(S, y);
```

The following pseudocode instruction is problematic. Why?

```
...
swap the two elements at the front of queue Q
...
```

❖ The Abstract RAM Model

RAM = Random Access Machine

- A CPU (central processing unit)
- A potentially unbounded bank of memory cells
 - each of which can hold an arbitrary number, or character
- Memory cells are numbered, and accessing any one of them takes CPU time

❖ Primitive Operations

- Basic computations performed by an algorithm
- Identifiable in pseudocode
- Largely independent of the programming language
- Exact definition not important (we will shortly see why)
- Assumed to take a constant amount of time in the RAM model

Examples:

- evaluating an expression
- indexing into an array
- calling/returning from a function

❖ Counting Primitive Operations

By inspecting the pseudocode ...

- we can determine the maximum number of primitive operations executed by an algorithm
- as a function of the input size

Example:

```
arrayMax(A):
  Input   array A of n integers
  Output maximum element of A
```

```

for loop {
  currentMax=A[0]
  for all i=1..n-1 do
    if A[i]>currentMax then
      currentMax=A[i]
    end if
  end for
  return currentMax
}
```

$A[0] \dots A[n-1]$ 1次
 $n + (n-1) = 2n-1$
 $2(n-1) = 2n-2$
 $n-1$ 次

 Total $5n-2$

Analysis of Algorithms ◇ COMP2521 (20T3) ◇ Week 01b ◇ [14/60]

❖ Estimating Running Times

Algorithm **arrayMax** requires $5n - 2$ primitive operations in the worst case

- best case requires $4n - 1$ operations (why?)

Define:

- a ... time taken by the fastest primitive operation
- b ... time taken by the slowest primitive operation

Let $T(n)$ be worst-case time of **arrayMax**. Then

$$a \cdot (5n - 2) \leq T(n) \leq b \cdot (5n - 2)$$

Hence, the running time $T(n)$ is bound by two linear functions

❖ ... Estimating Running Times

Seven commonly encountered functions for algorithm analysis

- Constant ≈ 1
- Logarithmic $\approx \log n$ *grow slowly, best*
- Linear $\approx n$
- N-Log-N $\approx n \log n$
- Quadratic $\approx n^2$
- Cubic $\approx n^3$
- Exponential $\approx 2^n$
grows double, quickly, worst

❖ ... Estimating Running Times

In a log-log chart, the slope of the line corresponds to the growth rate of the function

growing $n! > 2^n > n^3 > n^2 > n \log n > n > \log n > 1$

See the following chart :

<http://bigocheatsheet.com/>

❖ ... Estimating Running Times

The growth rate is not affected by constant factors or lower-order terms

- Examples:

- $10^2n + 10^5$ is a linear function
- $10^5n^2 + 10^8n$ is a quadratic function

❖ ... Estimating Running Times

Changing the hardware/software environment

- affects $T(n)$ by a constant factor
- but does not alter the growth rate of $T(n)$

⇒ Linear growth rate of the running time $T(n)$ is an intrinsic property of algorithm **arrayMax**

固有特性

❖ Exercise : Estimating running times

```
matrixProduct(A,B):
```

```
  Input  n×n matrices A, B
```

```
  Output n×n matrix A·B
```

```
  for all i=1..n do
```

```
    for all j=1..n do
```

```
      C[i,j]=0
```

```
      for all k=1..n do
```

```
        C[i,j]=C[i,j]+A[i,k]·B[k,j]
```

```
      end for
```

```
    end for
```

```
  end for
```

```
  return C
```

$$\begin{aligned}
 n+(n+1) &= 2n+1 \\
 n(2n+1) &= n^2(2n+1) \\
 n^2(2n+1) &= n^3 \cdot 5 \quad ?
 \end{aligned}$$

1

$$\text{Total} \quad 7n^3+4n^2+3n+2$$

number of primitive operations

❖ Big-Oh Notation

Given functions $f(n)$ and $g(n)$, we say that

$f(n)$ is $O(g(n))$

if there are positive constants c and n_0 such that

$$f(n) \leq c \cdot g(n) \quad \forall n \geq n_0$$

❖ ... Big-Oh Notation

Example: function $2n + 10$ is $O(n)$

$\bullet \quad 2n + 10 \leq c \cdot n$
 $\Rightarrow (c - 2)n \geq 10$
 $\Rightarrow n \geq 10 / (c - 2)$

- pick $c = 3$ and $n_0 = 10$

$n \geq \frac{10}{1} = 10$
 $n_0 = 10$

❖ ... Big-Oh Notation

Example: function n^2 is not $O(n)$

- $n^2 \leq c \cdot n$
 $\Rightarrow n \leq c$
- inequality cannot be satisfied since c must be a constant

1. $7n-2$ is $O(n)$

need $c>0$ and $n_0 \geq 1$ such that $7n-2 \leq c \cdot n$ for $n \geq n_0$

\Rightarrow true for $c=7$ and $n_0=1$

$$\begin{aligned} 1. \quad n(7-c) &\leq 2 \\ n &\leq \frac{2}{7-c} \quad n \geq \frac{2}{7-c} \\ 1 &\geq 0 \text{ true} \end{aligned}$$

2. $3n^3 + 20n^2 + 5$ is $O(n^3)$

need $c>0$ and $n_0 \geq 1$ such that $3n^3 + 20n^2 + 5 \leq c \cdot n^3$ for $n \geq n_0$

\Rightarrow true for $c=4$ and $n_0=21$

3. $3 \cdot \log n + 5$ is $O(\log n)$

need $c>0$ and $n_0 \geq 1$ such that $3 \cdot \log n + 5 \leq c \cdot \log n$ for $n \geq n_0$

\Rightarrow true for $c=8$ and $n_0=2$

$$\log n$$

$$\log n (3-c) \leq -5$$

$$\log n \geq \frac{5}{3-c}$$

$$n \geq e^{\frac{5}{3-c}}$$

$$2 \geq 0.368 \text{ true}$$

❖ Big-Oh Rules

- If $f(n)$ is a polynomial of degree $d \Rightarrow f(n)$ is $O(n^d)$
 - lower-order terms are ignored
 - constant factors are ignored
- Use the smallest possible class of functions
 - say " $2n$ is $O(n)$ " instead of " $2n$ is $O(n^2)$ "
- Use the simplest expression of the class
 - say " $3n + 5$ is $O(n)$ " instead of " $3n + 5$ is $O(3n)$ "

<< ^ >>

❖ Big-Oh and Rate of Growth

- Big-Oh notation gives an upper bound on the growth rate of a function
 - "f(n) is $O(g(n))$ " means growth rate of f(n) no more than growth rate of g(n)
- use big-Oh to rank functions according to their rate of growth

$$f(n) \leq C \cdot g(n)$$

	f(n) is $O(g(n))$	g(n) is $O(f(n))$
g(n) grows faster	yes	no
f(n) grows faster	no	yes
same order of growth	yes	yes

$$\sum_{i=1}^n i = \frac{n(n+1)}{2} = \frac{n^2 + n}{2}$$

Show that $\sum_{i=1}^n i$ is $O(n^2)$

which is $O(n^2)$

$$\frac{n^2 + n}{2}$$

$$\implies n^2 + n$$

constant factors are ignored

$$\Downarrow$$

lower-order terms are ignored

$$n^2$$

❖ Asymptotic Analysis of Algorithms

Asymptotic analysis of algorithms determines running time in big-Oh notation:

- find worst-case number of primitive operations as a function of input size
- express this function using big-Oh notation

Example:

- algorithm **arrayMax** executes at most $5n - 2$ primitive operations
⇒ algorithm **arrayMax** "runs in $O(n)$ time"

Constant factors and lower-order terms eventually dropped
⇒ can disregard them when counting primitive operations

❖ Example: Computing Prefix Averages

- The *i*-th prefix average of an array *X* is the average of the first *i* elements:

$$A[i] = (X[0] + X[1] + \dots + X[i]) / (i+1)$$

A[i] is average

NB. computing the array *A* of prefix averages of another array *X* has applications in financial analysis

❖ ... Example: Computing Prefix Averages

A quadratic algorithm to compute prefix averages:

```

prefixAverages1(X):
  Input array X of n integers
  Output array A of prefix averages of X

  for all i=0..n-1 do
    s=X[0]
    for all j=1..i do
      s=s+X[j]
    end for
    A[i]=s/(i+1)
  end for
  return A

```

Complexity analysis (handwritten notes):

- $O(n) \rightarrow 2n-1$ (for the first loop)
- $O(n)$ (for the second loop)
- $O(n^2)$ (for the inner loop, $n(2n-1)$)
- $O(n^2)$ (for the inner loop)
- $O(n)$ (for the assignment $A[i]=s/(i+1)$)
- $O(1)$ (for the return statement)

$$2 \cdot O(n^2) + 3 \cdot O(n) + O(1) = O(n^2)$$

⇒ Time complexity of algorithm **prefixAverages1** is $O(n^2)$

<< ^ >>

❖ ... Example: Computing Prefix Averages

The following algorithm computes prefix averages by keeping a running sum:

```

prefixAverages2(X):
|   Input   array X of n integers
|   Output array A of prefix averages of X
|
|   s=0
|   for all i=0..n-1 do
|       s=s+X[i]
|       A[i]=s/(i+1)
|   end for
|   return A

```

 $O(n)$ $O(n)$ $O(n)$ $O(1)$ $3O(n) + O(1)$

↓

 $O(n)$

Thus, **prefixAverages2** is $O(n)$

❖ Example: Binary Search

The following recursive algorithm searches for a value in a **sorted** array:

```

search(v,a,lo,hi):
  Input  value v
         array a[lo..hi] of values
  Output true if v in a[lo..hi]
         false otherwise

  mid=(lo+hi)/2
  if lo>hi then return false
  if a[mid]=v then
    return true
  else if a[mid]<v then
    return search(v,a,mid+1,hi)
  else
    return search(v,a,lo,mid-1)
  end if

```

v → value

a → array

lo → low value

hi → high value

O(1)

O(n)

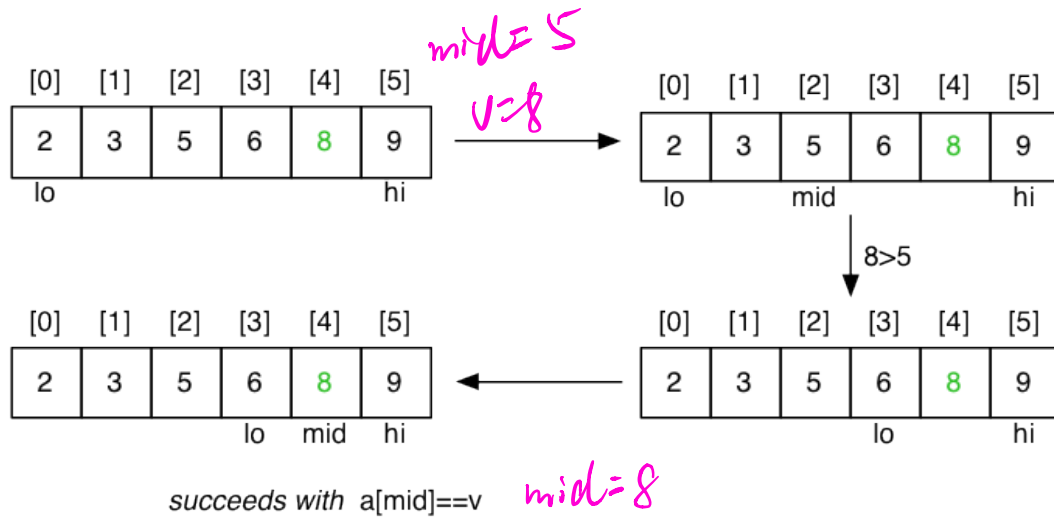

O(log n)

O(n log n)

repeat this function

❖ ... Example: Binary Search

Successful search for a value of 8:

❖ ... Example: Binary Search

Unsuccessful search for a value of 7:

❖ ... Example: Binary Search

Cost analysis:

- C_i = #calls to **search()** for array of length i
- for best case, $C_n = 1$
- for $a[i..j]$, $j < i$ (length=0)
 - $C_0 = 0$
- for $a[i..j]$, $i \leq j$ (length= n)
 - $C_n = 1 + C_{n/2} \Rightarrow C_n = \log_2 n$

Thus, binary search is $O(\log_2 n)$ or simply $O(\log n)$ (why?)

❖ ... Example: Binary Search

Why logarithmic complexity is good:

❖ Math Needed for Complexity Analysis

- Summations
- Logarithms
 - $\log_b(xy) = \log_b x + \log_b y$
 - $\log_b(x/y) = \log_b x - \log_b y$
 - $\log_b x^a = a \log_b x$
 - $\log_b a = \log_x a / \log_x b$
- Exponentials
 - $a^{(b+c)} = a^b a^c$
 - $a^{bc} = (a^b)^c$
 - $a^b / a^c = a^{(b-c)}$
 - $b = a^{\log_a b}$
 - $b^c = a^{c \cdot \log_a b}$
- Proof techniques
- Summation (addition of sequences of numbers)
- Basic probability (for average case analysis, randomised algorithms)

❖ Exercise : Analysis of Algorithms

What is the complexity of the following algorithm?

```
splitList(L):
```

```
|   Input   non-empty linked list L
```

```
|   Output L split into two halves
```

```
|
```

```
|   // use slow and fast pointer to traverse L
```

```
|   slow=head(L), fast=head(L).next
```

```
|   while fast≠NULL ∧ fast.next≠NULL do
```

```
|       slow=slow.next, fast=fast.next.next // advance pointers
```

```
|   end while
```

```
|   cut L between slow and slow.next
```

$O(L)$?

❖ Exercise : Analysis of Algorithms

What is the complexity of the following algorithm?

```

binaryConversion(n):
|   Input positive integer n
|   Output binary representation of n on a stack
|
|   create empty stack S
|   while n>0 do
|       |   push (n mod 2) onto S
|       |   n=[n/2]
|   end while
|   return S

```

Handwritten notes in pink:

- $O(1)$ next to "create empty stack S"
- $O(\log n)$ next to the while loop
- $n/2/2/2 \dots \approx 0$ next to n=[n/2]
- $O(1)$ next to "return S"

Assume that creating a stack and pushing an element both are $O(1)$ operations ("constant")

$O(\log n)$

❖ Relatives of Big-Oh

big-Omega

- $f(n)$ is $\Omega(g(n))$ if there is a constant $c > 0$ and an integer constant $n_0 \geq 1$ such that

$$f(n) \geq c \cdot g(n) \quad \forall n \geq n_0$$

$$(f(n) \leq c \cdot g(n) \quad O(g(n)))$$

big-Theta

- $f(n)$ is $\Theta(g(n))$ if there are constants $c', c'' > 0$ and an integer constant $n_0 \geq 1$ such that

$$c' \cdot g(n) \leq f(n) \leq c'' \cdot g(n) \quad \forall n \geq n_0$$

❖ ... Relatives of Big-Oh

- $f(n)$ is $\mathcal{O}(g(n))$ if $f(n)$ is asymptotically less than or equal to $g(n)$
- $f(n)$ is $\mathcal{\Omega}(g(n))$ if $f(n)$ is asymptotically greater than or equal to $g(n)$
- $f(n)$ is $\mathcal{\Theta}(g(n))$ if $f(n)$ is asymptotically equal to $g(n)$

❖ ... Relatives of Big-Oh

Examples:

- $\frac{1}{4}n^2$ is $\Omega(n^2)$ *equal*

- need $c > 0$ and $n_0 \geq 1$ such that $\frac{1}{4}n^2 \geq c \cdot n^2$ for $n \geq n_0$

- let $c = \frac{1}{4}$ and $n_0 = 1$

$\frac{1}{4} \geq c$ true

$$f(n) \geq c \cdot g(n)$$

$$f(n) = \frac{1}{4}n^2$$

- $\frac{1}{4}n^2$ is $\Omega(n)$

- need $c > 0$ and $n_0 \geq 1$ such that $\frac{1}{4}n^2 \geq c \cdot n$ for $n \geq n_0$

- let $c = 1$ and $n_0 = 2$

$$\frac{1}{4}n \geq c$$

$$\frac{1}{4} \geq 1 \text{ false}$$

- $\frac{1}{4}n^2$ is $\Theta(n^2)$

- since $\frac{1}{4}n^2$ is in $\Omega(n^2)$ and $O(n^2)$

$$O(n^2) : \frac{1}{4}n^2 \leq c \cdot n^2 \quad \frac{1}{4} \leq c \quad c=1 \quad n_0=1 \text{ true}$$

❖ Complexity Classes

Problems in Computer Science ...

- some have polynomial worst-case performance (e.g. n^2)
- some have exponential worst-case performance (e.g. 2^n)

Classes of problems:

- P = problems for which an algorithm can compute answer in polynomial time
- NP = includes problems for which no P algorithm is known

Beware: NP stands for "nondeterministic, polynomial time (on a theoretical Turing Machine)"

❖ ... Complexity Classes

Computer Science ^{术语} jargon for difficulty:

- ^{易处理} tractable ... have a polynomial-time algorithm (useful in practice)
- ^{棘手的} intractable ... no tractable algorithm is known (feasible only for small n)
- non-computable ... no algorithm can exist

Computational complexity theory deals with different degrees of intractability ^{难解性}

❖ Generate and Test Algorithms

In scenarios where

- it is simple to test whether a given state is a solution
- it is easy to generate new states (preferably likely solutions)

then a generate and test strategy can be used.

It is necessary that states are generated systematically

- so that we are guaranteed to find a solution, or know that none exists
 - some randomised algorithms do not require this, however (more on this later in this course)

❖ ... Generate and Test Algorithms

Simple example: checking whether an integer n is prime

- generate/test all possible factors of n
- if none of them pass the test $\Rightarrow n$ is prime

Generation is straightforward:

- produce a sequence of all numbers from 2 to $n-1$

Testing is also straightforward:

- check whether next number divides n exactly

❖ ... Generate and Test Algorithms

Function for primality checking:

```
isPrime(n):
|   Input natural number n
|   Output true if n prime, false otherwise
|
|   for all i=2..n-1 do           // generate  $O(n)$ 
|   |   if n mod i = 0 then       // test
|   |   |   return false         // i is a divisor => n is not prime
|   |   end if
|   end for
|   return true                   // no divisor => n is prime  $O(1)$ 
```

Complexity of **isPrime** is $O(n)$

Can be optimised: check only numbers between 2 and $\lfloor \sqrt{n} \rfloor \Rightarrow O(\sqrt{n})$

❖ Example: Subset Sum

Problem to solve ...

Is there a subset S of these numbers with $\text{sum}(S)=1000$?

34, 38, 39, 43, 55, 66, 67, 84, 85, 91,
101, 117, 128, 138, 165, 168, 169, 182, 184, 186,
234, 238, 241, 276, 279, 288, 386, 387, 388, 389

General problem:

- given n integers and a target sum k
- is there a subset that adds up to exactly k ?

❖ ... Example: Subset Sum

Generate and test approach:

```
subsetsum(A,k):  
|   Input set A of n integers, target sum k  
|   Output true if  $\sum_{b \in B} b = k$  for some  $B \subseteq A$   
|           false otherwise  
  
|   for each subset  $S \subseteq A$  do 2n  
|       if sum(S)=k then  
|           return true  
|       end if  
|   end for  
|   return false
```

- How many subsets are there of n elements?
- How could we generate them?

❖ ... Example: Subset Sum

Given: a set of n distinct integers in an array A ...

- produce all subsets of these integers

A method to generate subsets:

- represent sets as n bits (e.g. $n=4$, 0000, 0011, 1111 etc.)
- bit i represents the i^{th} input number
- if bit i is set to 1, then $A[i]$ is in the subset
- if bit i is set to 0, then $A[i]$ is not in the subset
- e.g. if $A[] = \{1, 2, 3, 5\}$ then 0011 represents $\{1, 2\}$

❖ ... Example: Subset Sum

Algorithm:

```
subsetsum1(A,k):  
|   Input   set A of n integers, target sum k  
|   Output true if  $\sum_{b \in B} b = k$  for some  $B \subseteq A$   
|           false otherwise  
  
|   for s=0.. $2^n-1$  do  
|   |   if k =  $\sum$  ( $i^{\text{th}}$  bit of s is 1) A[i] then  
|   |       return true  
|   |   end if  
|   end for  
|   return false
```

Obviously, **subsetsum1** is $O(2^n)$

❖ ... Example: Subset Sum

Cost analysis:

- C_i = #calls to **subsetsum2**() for array of length i
- for best case, $C_n = C_{n-1}$ (why?) ?
- for worst case, $C_n = 2 \cdot C_{n-1} \Rightarrow C_n = 2^n$

Thus, **subsetsum2** also is $O(2^n)$

❖ ... Example: Subset Sum

Subset Sum is typical member of the class of **NP-complete problems**

- intractable ... only algorithms with exponential performance are known
 - increase input size by 1, double the execution time
 - increase input size by 100, it takes $2^{100} = 1,267,650,600,228,229,401,496,703,205,376$ times as long to execute
- but **if you can find** a polynomial algorithm for Subset Sum, **then any other NP-complete problem becomes P!**
